SIGNALING PROTOCOL COMMUNICATION NETWORKS

(57) Advertising available resource information for a link in a communication network is provided. The network uses a source routing protocol. The source routing protocol uses the available resource advertisements for identifying a path for a call routed through the node in the network. The method advertises the available resource information for the node to adjacent nodes linked to the node in the network when the node receives a request for a connection to be routed over the link, the request seeking resources exceeding available resources for the link.

Call scenarios:

1. Call request's bandwidth below or equal to the Current AvCR value
Call is admitted, a new advertisement may be issued but only if a significant bandwidth change took place.
2. Call Request bandwidth above the Current AvCR value but below or equal to the Last Advertised AvCR value
Call is rejected in CAC. A new advertisement is issued to update network's view of the node's bandwidth and the significant bandwidth change range is re-computed.
3. Call Request bandwidth above the Last Advertised AvCR value
Call is rejected in CAC. No new advertisement is issued, since the Last Advertised AvCR value should make other nodes reject the call in GCAC.

Call is rejected in CAC. No new advertisement is issued, since the Last Advertised AvCR value should make other nodes reject the call in GCAC.

(57) Abrégé/Abstract:

Advertising available resource information for a link in a communication network is provided. The network uses a source routing protocol. The source routing protocol uses the available resource advertisements for identifying a path for a call routed through the node in the network. The method advertises the available resource information for the node to adjacent nodes linked to the node in the network when the node receives a request for a connection to be routed over the link, the request seeking resources exceeding available resources for the link.

ABSTRACT

Advertising available resource information for a link in a communication network is provided. The network uses a source routing protocol. The source routing protocol uses the available resource advertisements for identifying a path for a call routed through
5 the node in the network. The method advertises the available resource information for the node to adjacent nodes linked to the node in the network when the node receives a request for a connection to be routed over the link, the request seeking resources exceeding available resources for the link.

**TITLE: SYSTEM AND METHOD FOR CALL-BLOCKING-TRIGGERED
 TOPOLOGY UPDATES IN SOURCE ROUTED SIGNALING
 PROTOCOL COMMUNICATION NETWORKS**

5 FIELD OF THE INVENTION

The invention relates generally to communication systems, and more particularly, to a method and system for call-blocking-triggered topology updates in source routed signaling protocol communication networks.

BACKGROUND OF THE INVENTION

10 Communication between a calling party (source) and a called party (destination) may be established over a communication network. Such a communication network may use source routing protocols in order to establish connections over which such communication can occur. Communication networks that support source routing protocols typically comprise a number of individual communication switches through
15 which calls are routed. A call set-up message is sent along a path through a number of intervening switches, or nodes, in order to establish the call.

In source routing protocols, each node in the network determines a path to the destination of a call based on current knowledge of that node of the network topology. A source node encodes the computed path in a message used to setup a given connection, so
20 other nodes along the path can follow the computed path. As network topology changes (for example, nodes and links appear or disappear or bandwidth consumption changes) a path to a given destination may change. These changes are reflected in a path computed by the source node.

One type of topology change reported by nodes in the network is bandwidth
25 available on each link. As the bandwidth on a given link changes, nodes at each end of the link report the new available bandwidth. Issuing an advertisement with each bandwidth change is usually not practical, as it would require significant resources to distribute the changes and to act upon them. These resources would often need to be

taken from resources available for setup of calls, hence decreasing overall network efficiency. As result, a concept of “significant change” is used: a node advertises a change in available bandwidth only when the bandwidth changes by a value deemed significant from the last advertised value. The significant-change-based advertisements have the following drawback: decreases in bandwidth that do not cross the significant value bound are deemed “insignificant”, and hence are not advertised to the network. The other nodes in the network, unaware of the decrease in bandwidth, keep using the last advertised bandwidth of that link in their path computations, even though the actual value is less than this last advertised value. Any of these nodes can build a path that includes the above link because its last advertised bandwidth satisfies a bandwidth of a given call. However, if the bandwidth requirements of a call are greater than the bandwidth currently available on that link, the call blocks when a cross-connect on the link is attempted.

Private Network-Network Interface (PNNI) protocol is an example of a source routing protocol that advertises bandwidth changes using a concept of the significant change. PNNI provides two control parameters that define what is deemed significant bandwidth change on a link: Available Cell Rate Proportional Multiplier (AvCR_PM) and Available Call Rate Minimum Threshold (AvCR_mT). AvCR_PM specifies the percentage that the bandwidth of the link must change from the last advertised value for a change to be deemed significant. AvCR_mT is a minimum threshold, expressed as a percentage of the maximum cell rate, ensuring a non-zero range of insignificance. As the bandwidth on the link is being consumed AvCR_PM is used by the node to determine significant changes until the value based on AvCR_mT (i.e. link bandwidth * AvCR_mT) becomes bigger than that based on AvCR_PM. When this takes place no further advertisement is issued until the link’s bandwidth reaches zero or increases by the AvCR_mT-based value. When nodes in the network include the link in their paths as a result of its last outdated available bandwidth advertisement, and a call blocks, because it requires more bandwidth than the link’s current available bandwidth, the call is released. RELEASE message may indicate that the call blocked because the bandwidth on the link was not available, and may include the current available bandwidth (AvCR) on the link that blocked the call. An alternate routing may take place to attempt to avoid the blocked link. Such behaviour has the following drawbacks:

- 3 -

1. A node launching the call performs a re-route for that call around the blocked link but, since no update to the link's available bandwidth for all service categories occurs the outdated link information is still used in routing subsequent calls. This means that an unnecessary load is presented to the network for calls that try to use the link but fail because of an inadequate bandwidth. It will be appreciated that outdated link information is used only if AvCR information is included for the link. Typically, only an AvCR for a service category for a call is included in a RELEASE message;
 2. The overall call's setup latency increases as calls block and need to be alternate routed;
 3. In an extreme case, a call may fail to be setup if each routing attempt experiences the above-described problem; and
 4. Only a source node or at most nodes along the path are informed about new available bandwidth when the call fails.
- There is a need for a routing system to address aspects of shortcomings of the prior art signaling systems.

SUMMARY

In a first aspect, a method of advertising information related to available resources for a link in a communication network is provided. The network uses a source routing protocol using the advertised information for identifying a path to route a call. The method comprises advertising information to adjacent nodes linked to the node when the node receives a request for a connection, the request seeking resources exceeding the available resources for the link on the node being used to route the call.

The method may comprise having adjacent nodes propagating the received information to their adjacent nodes, to update the entire network with the new information.

The method may advertise the information when the request seeks less resources
5 than resources previously advertised as available for the link.

The method may be used in an ATM communication network.

The method may be used where the source routing protocol is a PNNI protocol.

Further the method may have the information contained in a resource availability information group (RAIG).

10 Further still the RAIG may be contained within a PNNI Topology State Element (PTSE) describing any element of PNNI network topology like horizontal link, up-link, summary address, or exterior reachable address.

Still further, the method may have the information related to available bandwidth information.

15 In a second aspect, an apparatus for advertising information relating to available resources for a node in a communication network is provided. The communication network uses a source routing protocol for identifying a path for a call routed utilizing the information related to the link. The apparatus comprises a communication switch associated with the node and a procedure operating on the switch for advertising the
20 information relating to the available resources for links of the switch to adjacent switches in the network. The switch advertises the information relating to the available resources when the switch receives a request for a connection to be routed over the link and the request seeks resources exceeding the available resources for the link.

The apparatus may have the switch advertising the information relating to the available resources when the request seeks less resources than resources previously advertised as available for the link.

The apparatus may be used in an ATM network.

5 The apparatus may have the source routing protocol as a PNNI protocol.

The apparatus may have the the information is contained within a resource availability information group (RAIG).

The apparatus may have the RAIG contained within a PNNI Topology State Element (PTSE).

10 The apparatus may have the information as available bandwidth information.

In other aspects, the invention provides various combinations and subsets of the aspects described above.

BRIEF DESCRIPTION OF THE DRAWINGS

15 For a better understanding of the present invention and to show more clearly how it may be carried into effect, reference will now be made, by way of example, to the accompanying drawings which show the preferred embodiment of the present invention in which:

20 Figure 1 illustrates a block diagram of a data communication network in accordance with an embodiment of the present invention;

Figure 2 illustrates a block diagram of a bandwidth monitoring processor in accordance with an embodiment of Fig. 1;

Figure 3 illustrates an example bandwidth usage and advertisements issued by the embodiment of Fig. 1; and

Figure 4 illustrates a block diagram of a connection processor in accordance with an embodiment of Fig. 1.

DETAILED DESCRIPTION OF THE EMBODIMENTS

5 The description which follows, and the embodiments therein, are provided by way of illustrating an example, or examples, of particular embodiments of principles of the present invention. These examples are provided for the purpose of explanation, and not limitations, of those principles. In the description which follows, like elements are marked throughout the specification and the drawings with the same respective reference numerals.

10 Generally, the embodiment provides a method and apparatus for communicating and utilizing resource information in a communication network that utilizes source routing and significant resource change detection.

By understanding bandwidth information as it relates to the network topology, source nodes generating connection set-up messages can route the connection set-up
15 messages in an intelligent manner that avoids portions of the network, where bandwidth may not support bandwidth requirements for the connection being routed.

Aspects of the embodiment can be better understood with reference to Figures 1-4. Figure 1 illustrates a communication network 100, which may be a packet- or cell-based communication network. The communication network 100 may be an
20 asynchronous transfer mode (ATM) network that uses ATM cells to carry data traffic through the network. The network 100 allows the originating parties 10 to communicate with the destination parties 20 by establishing a connection through the various switches 30-36 included in the network 100. Each of the originating and destination parties 10 and 20 may be a router, a network coupled to a router, and or an end user device such as a
25 personal computer, facsimile machine, video telephone, or any device that receives and or transmits data via a communication network. When an originating party 10 requests that a connection be established with a destination party 20, the originating switch A 30 attempts to establish a connection with the destination switch D 33 such that packets or

cells may traverse the network along the connection and be delivered to the destination party 20.

Source routing protocols allow each node within the network to determine a complete path to a particular destination based on that node's knowledge of the network topology. Typically, each of the various switches, or nodes, within the network stores a
5 routing table or other database that includes parameters concerning the various links (i.e. topology) of the network that may be used in routing calls. When a path to a particular destination is to be determined, the table is consulted to determine a path to the destination. The selection of the path may include determining the most efficient path,
10 where various criteria such as cost, bandwidth availability, and the like are taken into account. Only the last advertised values for such criteria are used. These values may be different from the current values for these criteria especially, if a "significant change" concept is employed in updating the network with changes in values of some of these criteria.

15 For example, if the originating switch A 30 wishes to establish a connection with the destination switch D 33, a likely path may route the connection through the switch B 31 and the switch C 32. The path is selected by the source node that determines the path satisfies call's bandwidth requirements based on the last advertised bandwidth by the nodes in the network. If the bandwidth available on link to egress switch C32 does not
20 satisfy the call, because the link's bandwidth decreased but the change has been deemed insignificant, the originating switch A 30 issues a connection set-up message that traverses the network along the determined path and establishes the connection. The connection set-up message blocks on a link the call uses to egress switch C 32, because the link does not have sufficient bandwidth to handle the call. In prior art systems, the
25 node C 32 issues a RELEASE message to the source node of the call that may include the current AvCR on the link and the fact that the call blocked because of the bandwidth not being available. The call may then be rerouted by the source node to avoid either that link, or that node entirely. However, any subsequent calls from the source node or from any other node in the network requiring more bandwidth than available on the link that

blocked the call would try to utilize the link again if the outdated, last advertised bandwidth value satisfies call's bandwidth requirements.

The embodiment provides improved use of routing protocol in a communication network utilizing PNNI routing and signaling protocols. Specifics regarding PNNI routing and signaling protocol may be found in the "Private Network-Network Interface Specification Version 1.0" as published by the ATM Forum in March of 1996, which is incorporated herein by reference.

In particular, it is known that PNNI protocol specifies two separate, but interrelated, protocols and functions to achieve the goal of controlling the user packet or cell stream between nodes and networks. It defines how switched virtual connections are established and then automatically re-routed (if necessary) between network switches.

A PNNI routing protocol is defined for distributing topology information between switches and clusters of switches. This information is used to compute paths for the user packet or cell stream through the network. A hierarchy mechanism ensures that the PNNI protocol scales well for large world-wide ATM networks. A key feature of the PNNI hierarchy mechanism is its ability to automatically configure itself in networks in which the address structure reflects the topology. PNNI topology and routing is based on the well-known link-state routing technique.

A PNNI signaling protocol uses messages to establish point-to-point and point-to-multipoint connections across the ATM network. This protocol is based on the ATM Forum UNI signaling, with mechanisms added to support source routing, and crankback to earlier nodes and alternate routing of call setup requests to route around an intermediate node that blocks a call request.

PNNI routing applies to a network of lowest-level nodes. Data passes through lowest-level nodes to other lowest-level nodes and to end systems. End systems are points of origin and termination of connections. Physical links that attach a switching system at a node with a switching system at another node are duplex in that traffic may be carried in either direction. However, physical link characteristics may be different in

each direction, either because the capacities are different or because existing traffic loads differ. While efficient for smaller networks, this structure is less efficient for larger networks because each node must maintain the topology of the entire network.

5 To improve efficiency for larger networks, the PNNI hierarchy begins at the lowest level where the lowest-level nodes are organized into peer groups. A logical node in the context of the lowest hierarchy level is a lowest-level node. For simplicity, logical nodes are often denoted as nodes. A peer group is a collection of logical nodes, each of which exchanges information with other members of the group, such that all members maintain an identical view of the group.

10 Each node communicates with its adjacent node neighbors and thereby determines its local state information. This state information includes the identity and peer group membership of the node's immediate neighbors, and the status of its links to the neighbors. Each node then bundles its state information in PNNI Topology State Elements (PTSEs), which are reliably flooded throughout the peer group.

15 Flooding is the reliable hop-by-hop propagation of PTSEs throughout a peer group. It ensures that each node in a peer group maintains an identical topology database. Flooding is the advertising mechanism in PNNI. In essence, the flooding procedure is as follows. PTSEs are encapsulated within PNNI topology state packets (PTSPs) for transmission. When a PTSP is received, its component PTSEs are examined. Each PTSE
20 is acknowledged by encapsulating information from its PTSE header within an Acknowledgment Packet, which is sent back to the sending neighbor. If the PTSE is new or of more recent origin than the node's current copy, it is installed in the topology database and flooded to all neighbor nodes except the one from which the PTSE was received. A PTSE sent to a neighbor is periodically retransmitted until acknowledged.

25 PTSEs are the smallest collection of PNNI routing information that is flooded as a unit among all logical nodes within a peer group. A topology database of a node consists of a collection of all PTSEs received, which represent present view of that node of the PNNI routing domain. In particular the topology database provides all the information

required to compute a route from the given node to any address reachable in or through that routing domain.

Every node generates a PTSE that describes its own identity and capabilities, as well as information used in establishing the PNNI hierarchy. This is referred to as the nodal information. PTSEs contain, among other things, topology state parameters (i.e. link state parameters, which describe the characteristics of logical links, and nodal state parameters, which describe the characteristics of nodes). Flooding is an ongoing activity, i.e. each node issues PTSPs with PTSEs that contain updated information. The PTSEs contained in topology databases are subject to aging and get removed after a predefined duration if they are not refreshed by new incoming PTSEs. Only the node that originally originates a particular PTSE can reoriginate that PTSE.

The PNNI signaling protocol sets up the ATM connections for a call along the path determined by the routing protocol. The routing protocol uses two types of addresses, topology and end user, in a hierarchical manner. Through the exchange of topology information over PNNI links, every node learns about available bandwidth, cost, and quality of service (QoS) metrics in a hierarchically summarized version of the entire network. The source node uses these metrics to choose the best route to meet the requested required bandwidth and QoS criteria. The information about the source-to-destination path is computed at the source node and placed in a Designated Transit List (DTL) in the signaling message originated by the source. The DTL includes every node used in transit across the peer group. Intermediate nodes in the path expand the DTL in their domain, and crankback to find alternative paths if a node within their domain blocks the call.

The source PNNI node determines a path across the network based on the requested QoS and its knowledge of the network state obtained from the flooded PTSEs. In a dynamically changing network, the source node has only an imperfect approximation to the true network state. This imperfection occurs because the flooded information is always older than the current network state. The result is that the source node's

calculation of the best path as listed in the DTL may result in a call being blocked at a node because the next link does not have enough bandwidth to connect the call.

PTSEs are reissued both periodically, typically every half an hour, and on an event driven basis. It is not practical to reissue a PTSE for each bandwidth change as it would require significant resources to distribute the changes and to act upon them. These resources would often need to be taken from resources available for calls setup and decreasing overall network efficiency. As a result, the event that triggers a node to reissue its PTSE is a "significant change" in the available bandwidth, or the available cell rate (AvCR). AvCR is a measure of available bandwidth in cells per second for each traffic class as applied to a single network link or node in route determination.

As introduced earlier, changes in AvCR are measured in terms of a proportional difference from the last value advertised. A proportional multiplier (AvCR_PM) parameter, expressed as a percentage, provides flexible control over the definition of significant change for AvCR. There is also a minimum threshold (AvCR_mT) parameter, expressed as a percentage of the maximum cell rate, which ensures that the range of insignificance is non-zero.

Given a previous value for AvCR the network can establish an upper bound and a lower bound for AvCR values which define a range of insignificance. Any new value for AvCR computed that is within the bounds is not a significant change from the previous value. Any new value for AvCR that is outside the bounds is a significant change.

Once the available bandwidth on a link reaches some lower bound, all subsequent changes in bandwidth below this value are deemed insignificant until available bandwidth reaches 0.

The significant change based reissue of PTSEs has the following drawback: as a link's bandwidth decreases below the last advertised value but does not cross significant threshold, no new advertisement is issued for that link. The other nodes in the network, unaware of the decrease in bandwidth keep using the link's last advertised bandwidth in their path computations, even though the actual value is quite likely less than this last

advertised value. If the call's bandwidth requirements are greater than the bandwidth currently available on that link, the call blocks when it attempts to use that link

- 5 An advertisement message may use a resource availability information group (RAIG) data structure that is available in PNNI networks to communicate status of resources available at a node to other nodes. The RAIG includes information used to attach values of topology state parameters to nodes, links, and reachable addresses. Table A illustrates an example RAIG data set. The RAIG may be incorporated into the PTSC of the node.

TABLE A: Resource Availability Information Group Data Structure

Offset	Size (Octets)	Name	Function/Description
0	2	Type	Type = 128 for outgoing resource availability information Type = 129 for incoming resource availability information
2	2	Length

30	2	Cell Loss Ratio (CLP=0+1)	Encoded as the negative logarithm of the value, i.e., the value n in a message indicates a CLR of 10^{-n}
Optional GCAC related information:			
32	2	Type	Type = 160 (optional GCAC parameters)
34	2	Length	
36	4	Cell Rate	Units : cells/seconds

		Margin	
40	4	Variance Factor	Units of 2^{-8} . Note : the value of 0xFFFFFFFF for Variance Factor is used to indicate infinity

A separate available cell rate value may be advertised for each service category to describe the bandwidth available on the node to support new calls. The actual bandwidth available for new calls is determined by Call Admission Control (CAC). PNNI does not
5 change this, but rather advertises these values to other PNNI nodes to be used by GCAC when routing new calls.

Continuing with the example of the embodiment, Figure 2 illustrates a bandwidth monitoring processor 158 that may be included in the switch C 32 of the communication network 100 of Figure 1. The switch C 32 is capable of detecting connection admission
10 control failures because of unavailable bandwidth and providing a corresponding available bandwidth notification to additional switches, or nodes, within the communication network 100. Once communicated to the additional switches, the new available bandwidth information can be utilized to perform network functions. Such functions include sending connection set-up messages or control plane datagram
15 messages only when the bandwidth requirement is satisfied by the link's new advertised bandwidth value.

The bandwidth monitoring processor 158 included within the switch 150 includes a processing module 152 and memory 154. The processing module 152 may include a single processing entity or a plurality of processing entities. Such a processing entity
20 may be a microprocessor, microcontroller, microcomputer, digital signal processor, central processing unit, state machine, group of logic circuitry, or any device that processes information based on operational or programming instructions.

The memory 154 may be a single memory device or a plurality of memory devices. Such a memory device may be a read-only memory device, random access
25 memory device, floppy disk, hard drive memory, magnetic tape memory, DVD memory, or any device that stores digital information. Note that when the processing module 152 has one or more of its functions performed by a state machine or logic circuitry, the

memory containing the corresponding operational instructions is embedded within the state machine or logic circuitry.

5 The memory 154 stores programming or operating instructions that, when executed by the processing module 152, cause the processing module 152 to perform the method illustrated in Figure 3. Note that various steps included within the method of the embodiment may be performed utilizing hardware separate from the processing module 152 or included within the processing module 152 that is not dependent upon operational instructions included within the memory 154.

10 Accordingly, the embodiment utilizes and modifies aspects of PNNI signaling to improve advertisement of information for a node to address limitations of the known PNNI signaling and routing protocols. The embodiment is compliant with the PNNI communication standards.

15 An important feature of the embodiment is a triggering mechanism for advertising information related to a link. When the call blocks on a link used to egress switch C 32 because the link does not satisfy call's bandwidth requirements, the embodiment provides the means to communicate the new available bandwidth on the link to all nodes in the network. In addition to prior art procedures described above, switch C 32 triggers a new bandwidth advertisement containing the current available bandwidth for the link that blocked the call. Furthermore, switch C 32 may elect to issue the advertisement only if
20 the last advertised bandwidth for the link satisfies the call's bandwidth requirements, thus ensuring that only a single advertisement is issued in case of multiple calls requesting the same bandwidth that cannot be provided. The new advertisement updates network's view of the link and allows all nodes in the network, including the source node A 30, to exclude the link for calls that require more bandwidth than currently available on the link.

25 Using PNNI, the embodiment may be implemented by issuing a new horizontal link, up-link, or reachable address (whichever applies) PTSE advertisement whenever a call blocks as described above. The PTSE advertisement may include an appropriate RAIG, as described in Table A. New bandwidth information may be included in the field "Available Cell Rate" of Table A.

It will be appreciated that the embodiment provides the following:

1. A mechanism to reduce call blocking by updating network topology as needed when the calls block because of the out-of-date advertisements;
2. A mechanism to decrease the call setup latency and network load. Nodes
5 can quickly react to notification of blockage of calls and avoid links that have inadequate resources;
3. A mechanism to decrease probability of call failing t as again network topology is updated as soon as the old advertisement negatively affect setup of calls; and
- 10 4. A mechanism to decrease network resources required to update bandwidth changes, as significant change can be defined more conservatively allowing network to re-advertise new bandwidth values only when the last advertised values cause other nodes to block the calls.

15 The mechanism of the embodiment ensures the AvCR advertisements occur when the calls block because of the lack of bandwidth in the 0 to $\text{MaxCR} \times \text{AvCR_MT}$ node bandwidth range and when the significant change in node advertisements is configured too conservatively (i.e. calls start blocking in CAC before the node advertises significant bandwidth change as the available bandwidth decreases).

20 Referring to Figs. 1 and 3, an example of the implementation of the embodiment in PNNI routing is shown. Here, the link the call uses to egress node C 32 is an OC-12 trunk group having a MaxCR of approximately 620 Mbps. Accordingly, with a value of AvCR_MT of 1%, the smallest possible value in the embodiment, all available bandwidth changes, when the available bandwidth is between 0 Mbps to 6.2 Mbps, are deemed insignificant, and thus are not advertised.

25 In a first scenario, a call is requesting bandwidth in range 300 which is below the current AvCR value. The call is admitted. No new advertisement is issued for this node, since the bandwidth has yet not reached 0 Mbps (as per PNNI Specification 1.0).

In a second scenario, a call is requesting bandwidth in range 302 which is above the current AvCR value, but below the last advertised AvCR value. For example, node F 35 in the network 100 is source-routing 5 Mbps calls, i.e. in bandwidth 302, such that the DTL paths include the OC-12 link on node C 32 (the node is included, since the last
5 advertised bandwidth satisfies calls' bandwidth requirements). Accordingly, the calls are sent using the computed paths through node C 32, block at node C 32, and are cranked back towards the source node, which then needs to re-route the calls.

In absence of the mechanism implemented in the embodiment, the above scenario continues for all call attempts that require more than 1.5 Mbps, i.e. in the range of
10 bandwidth 302, until either one of the following occurs:

1. Bandwidth on the node increases enough to accept the blocked calls;
2. Bandwidth on the node drops to 0 and a new advertisement is issued; or
3. PNNI Protocol event causes a new advertisement that will have an up-to-date node's data.

15 However, with the mechanism of the embodiment, the first blocked call triggers a new advertisement with the updated AvCR value of 1.5 Mbps, i.e. in the range of bandwidth 302. The source node and all other nodes in the network receive the new advertisement, re-compute their routing tables, and no longer use the OC-12 link on node C32 to route 5 Mbps calls (the link no longer satisfies calls' bandwidth requirements).
20 Note, that if the source node cannot correctly act on the new advertisement (i.e. does not perform GCAC during a path selection), the calls may still be routed using paths including the node and will keep failing in CAC. However, no new advertisement is issued in such cases, as the calls' required bandwidth is bigger than the last advertised value for the node.

25 If, in a third scenario, a call is requesting a bandwidth in range of 304 (a bandwidth exceeding the last advertised AvCR value), the call is rejected in CAC and no new advertisement is issued, since the call's requested bandwidth is bigger than the last advertised value.

Referring to Figure 4, an implementation of the embodiment is shown. Figure 4 illustrates the originating switch A 30 of Figure 1, which is shown to include a connection processor 138. The connection processor 138 enables the originating switch A 30, or any other switch within the network, to receive and interpret call block indication messages and apply them such that network efficiency is increased. The connection processor 138 includes a processing module 132 and memory 134. As before, the processing module 132 may include a variety of different processing entities, and the memory 134 may be one or more of a variety of different memory devices. A non-exhaustive list of potential processing entities and memory structures was identified with respect to the processing module 152 and the memory 154 described with respect to Figure 2, above.

The memory 134 stores programming or operating instructions that allow the processing module 132 to perform call re-routing. It will be appreciated by those skilled in the art that the re-routing may be implemented in software and hardware.

Switch A 30 may have a database containing network topology information and bandwidth availability information for the nodes in the network. The information in the database may be used by switch A 30 to create new paths in a path computation to either include or exclude a link, based on the bandwidth requested by a call going through the node.

It will be appreciated that other embodiments may trigger advertisements when a different resource, i.e. non-bandwidth resource, associated with a node undergoes similar consumption issues as with those for bandwidth, as described above.

It should be understood that the implementation of variations and modifications of the invention and its various aspects will be apparent to those of ordinary skill in the art, and that the invention is not limited to the specific embodiments described. It is therefore contemplated to cover by the present invention, any and all modifications, variations or equivalents that fall within the spirit and scope of the basic underlying principles disclosed and claimed herein.

CLAIMS

We claim:

1. A method of advertising information related to available resources for a link in a communication network, said network using a source routing protocol for identifying a path for a call routed utilizing said information related to said link, said method comprising advertising said information to adjacent nodes linked to said node when said node receives a request for a connection to be routed over said link, said request seeking requested resources exceeding current available resources for said link.
2. A method of advertising information related to available resources for a link as in claim 1, wherein said advertising information occurs when said request seeks less resources than resources previously advertised as available for said link.
3. A method of advertising information related to available resources for a link as in claim 1, wherein said communication network is an ATM network.
4. A method of advertising information related to available resources for a link as in claim 1, wherein said source routing protocol is a PNNI protocol.
5. A method of advertising information related to available resources for a link as in claim 4, wherein said information is contained within a resource availability information group (RAIG).

6. A method of advertising information related to available resources for a link as in claim 5, wherein said RAIG is contained within a PNNI Topology State Element (PTSE).

5 7. A method of advertising information related to available resources for a link as in claim 6, wherein said information is available bandwidth information.

8. A method of advertising information related to available resources for a link as in claim 1, wherein said adjacent nodes flood said information to be sent to each node in
10 said network.

8. An apparatus for advertising information relating to available resources for a node in a communication network, said communication network using a source routing protocol for identifying a path for a call routed utilizing said information related to said
15 link, said apparatus comprising:

a communication switch associated with said node; and

a procedure operating on said switch for advertising said information relating to said available resources for links of said switch to adjacent switches in said network, wherein said switch advertises said information relating to said available resources when
20 said switch receives a request for a connection to be routed over said link, said request seeking resources exceeding said available resources for said link.

9. An apparatus for advertising information relating to available resources for a node in a communication network as claimed in claim 8, wherein said switch advertises said information relating to said available resources when said request seeks less resources than resources previously advertised as available for said link.

5

10. An apparatus for advertising information relating to available resources for a node in a communication network as claimed in claim 8, wherein said communication network is an ATM network.

10 11. An apparatus for advertising information relating to available resources for a node in a communication network as claimed in claim 8, wherein said source routing protocol is a PNNI protocol.

12. An apparatus for advertising information relating to available resources for a node
15 in a communication network as claimed in claim 11, wherein said information is contained within a resource availability information group (RAIG).

13. An apparatus for advertising information relating to available resources for a node
in a communication network as claimed in claim 12, wherein said RAIG is contained
20 within a PNNI Topology State Element (PTSE).

- 21 -

14. An apparatus for advertising information relating to available resources for a node in a communication network as claimed in claim 13, wherein said information is available bandwidth information.

Figure 2

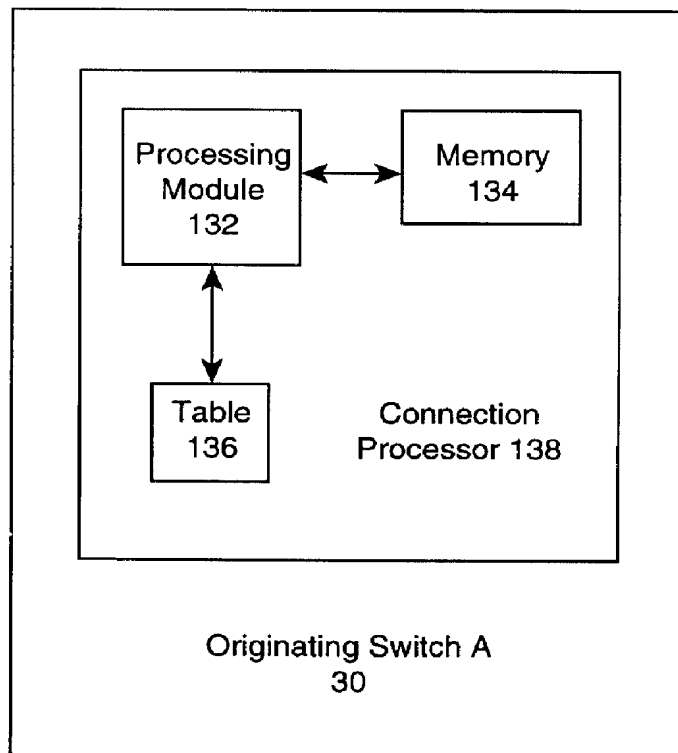

Figure 4

Call scenarios:

1. **Call request's bandwidth below or equal to the Current AvCR value**
Call is admitted, a new advertisement may be issued but only if a significant bandwidth change took place.
2. **Call Request bandwidth above the Current AvCR value but below or equal to the Last Advertised AvCR value**
Call is rejected in CAC. A new advertisement is issued to update network's view of the node's bandwidth and the significant bandwidth change range is re-computed.
3. **Call Request bandwidth above the Last Advertised AvCR value**
Call is rejected in CAC. No new advertisement is issued, since the Last Advertised AvCR value should make other nodes reject the call in GCAC.
